

**Book problems:** §4.1: 9 (ignore hint for (b); think geometrically), 10.

1. Let  $Q$  denote the quaternion group from §1.5.

(i) As the book notes, merely writing down relations doesn't guarantee that there exists a non-trivial group satisfying the relations (e.g., if we try to "define" a group by the condition that it be generated by an element  $g$  satisfying the relations  $g^3 = g^5 = 1$ , then it must be the trivial group). Get around this issue in the present case by checking that the matrices

$$\mathbf{i} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \mathbf{j} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

in  $\mathrm{GL}_2(\mathbf{C})$  satisfy the desired relations and generate a subgroup of  $\mathbf{GL}_2(\mathbf{C})$  of order exactly 8 (here,  $i \in \mathbf{C}$  is a fixed square root of  $-1$ ).

(ii) Work out all of the distinct subgroups of  $Q$ , and check they're all normal by inspection.

2. Let  $G$  be a group and  $H$  a subgroup.

(i) If  $H'$  is a subgroup of  $H$ , show that the various group indices are related by the equation  $[G : H'] = [G : H][H : H']$ , understood to implicitly include the assertion that if any two of the three are finite then so is the third (in which case this equation holds).

(ii) If  $G$  acts on the right on a set  $X$  and  $H$  is normal in  $G$ , show that the group  $G/H$  naturally acts on the right on the set  $X/H$ , and construct a natural bijection  $(X/H)/(G/H) \simeq X/G$ .

3. Let  $F$  be a field and  $V$  a vector space of dimension  $n > 0$  over  $F$ .

(i) Show that the center of  $G = \mathrm{GL}(V)$  is the subgroup of nonzero scalar multiplications ( $\simeq F^\times$ ).

(ii) Let  $V = \oplus V_i$  be a decomposition into a direct sum of (nonzero) subspaces. Let  $H \subseteq G$  be the subgroup which respects this decomposition (i.e., those elements carrying each  $V_i$  back into itself); in terms of a basis adapted the  $V_i$ 's, there are "block" matrices. Assume  $|F| > 2$ . By thinking about stable subspaces (don't use matrices!!!), describe  $N_G(H)$  and  $Z_G(H)$ , as well as  $N_G(H)/Z_G(H)$  (identify this latter quotient with a suitable symmetric group). Pay attention to  $V_i$ 's of the same dimension!

(iii) For an element  $g \in K = \mathfrak{S}_n$  generating a subgroup  $H$ , describe  $N_K(H)$ ,  $Z_K(H)$ , and  $N_G(K)/Z_G(K)$  in terms of the cycle decomposition of  $g$  (hint: look at orbits of  $g$ -action, the analogues of stable subspaces).

4. Let  $G$  be a finite abelian group,  $H$  a subgroup. Let  $\chi : H \rightarrow \mathbf{C}^\times$  be a group homomorphism.

(i) Show that the image  $\chi(H)$  consists of roots of unity.

(ii) If  $H'$  is a second subgroup of  $G$  and  $\chi' : H' \rightarrow \mathbf{C}^\times$  is a group homomorphism, then assuming  $\chi|_{H \cap H'} = \chi'|_{H \cap H'}$  shows that there exists a unique group homomorphism  $\tilde{\chi} : HH' \rightarrow \mathbf{C}^\times$  which restricts to  $\chi$  on  $H$  and  $\chi'$  on  $H'$  (must use that  $G$  is abelian!).

(iii) Show that the originally given  $\chi$  extends to a group homomorphism  $G \rightarrow \mathbf{C}^\times$ .

5. This exercise determines the structure of  $(\mathbf{Z}/p^r)^\times$  for any prime  $p$  and any  $r \geq 1$ .

(i) Assume  $p > 2$ . Show that  $a$  is an integer not divisible by  $p$ , then  $(1 + ap^i)^p = 1 + a'p^{i+1}$  for some  $a'$  not divisible by  $p$  (you'd better use somewhere that  $p \neq 2$ ). Deduce for any  $i \geq 0$  that that  $(1 + p)^r \equiv 1 \pmod{p^{i+1}}$  if and only if  $p^i | r$ . Give a counterexample to this when  $p = 2$ .

(ii) Fix  $p \geq 2$  and  $i \geq 1$ . Show that the natural reduction map  $\mathbf{Z}/p^i \rightarrow \mathbf{Z}/p$  induces a homomorphism of unit groups  $(\mathbf{Z}/p^i)^\times \rightarrow (\mathbf{Z}/p)^\times$ . But in HW1 we saw (conditional on a result to be shown later, if not known already) that  $(\mathbf{Z}/p)^\times$  is a cyclic group, since  $\mathbf{Z}/p$  is a *finite field*. Picking  $u \in (\mathbf{Z}/p^i)^\times$  lifting a generator of  $(\mathbf{Z}/p)^\times$ , deduce there must exist an element of  $(\mathbf{Z}/p^i)^\times$  of order  $p - 1$ . But in (i) you showed  $1 + p \pmod{p^i}$  has order  $p^{i-1}$ . Deduce that there exists an element of order  $p^{i-1}(p - 1)$ , and conclude that such an element is a generator (so  $(\mathbf{Z}/p^i)^\times$  is *cyclic*).

(iii) The case  $p = 2$  is a little different. By inspection,  $(\mathbf{Z}/2)^\times$  is cyclic, so now fix  $i \geq 2$  and consider  $G = (\mathbf{Z}/2^i)^\times$ . Let  $H$  be the subgroup of elements congruent to 1 mod 4 (i.e., the kernel of  $(\mathbf{Z}/2^i)^\times \rightarrow (\mathbf{Z}/4)^\times$ ). Show that every element in  $G$  can be *uniquely* written in the form  $\varepsilon \cdot h$  where  $\varepsilon = \pm 1$  and  $h \in H$ . To show  $H$  is cyclic (of what order?), prove a suitable variant on (i) by studying  $(1 + a \cdot 2^j)^2$  for  $j \geq 2$  and odd  $a$ .
